ALLOY-COATED BOILER PART AND METHOD OF WELDING

SELF-FLUXING ALLOY-COATED BOILER PART

TECHNICAL FIELD

5 [0001]

The present invention relates to a boiler part such as a tube part (hereinafter, referred to as "boiler tube") constituting a heat transfer tube in various types of boilers, or a plate material-tube material composite panel (hereinafter, referred to as "boiler furnace panel") constituting a furnace housing
10 with a cooling-water passage, and more specifically to a boiler part with alloy coating for improving durability and suitable to the welding, and a method of welding an alloy-coated boiler part.

BACKGROUND ART

[0002]

15 Firstly, taking an example of when exemplifying the boiler tube, in the past days when the operation temperature of the boiler was is lower than that in these days, and erosion/corrosion environment inside the furnace was is not so severe, that the steel tube for boiler (low alloy steel tube) was commonly used without coating taking into consideration of high temperature usability and with-
20 respect to mechanical characteristics, Although is made to be used in bare state is an ordinary use mode. The stainless tube, and further the titanium tube were also are used for the application of requiring corrosion resistance, such uses were however since coming expensive, not common because of the high costs be in- heavy use.

25 [0003]

In recent years, boilers a boiler with the form of recovering and utilizing

refuse incineration heat have increased heat increases, thereby in particular, problem of erosion (wear) is caused by combustion ash dust. In order to solve dust occurs, as a countermeasure for this problem, boilers with a specification for applying thermal spray coating of self-fluxing alloy (first alloy material) with high 5 excelling in erosion resistance are starting started to be commonly used, in heavy-usage.

However, the above described self-fluxing alloy coating is the coating which is left as subjected to the thermal-sprayed formation-by, for example, HVOF (High Velocity Oxygen Fuel) thermal spraying apparatus (that is, the coating it is 10 porous having coating, so pinholes reaching base metal herein after metal exist.— Hereinafter, referred to as "unmelted coating"); a self-fluxing alloy coating subjected to the melting process after thermal spraying is rarely used although melted coating is commonly heavily used in other application (for example, rollers for metal sheet processing line)(which the self-fluxing alloy coating is modified 15 from the porous coating into the dense coating, and is the coating provided with sufficient environment blocking function without with the above pinholes lost, and is the example of the "melted weld-deposition coating"); application of such self-fluxing alloy coating subjected to the melting process after thermal spraying is uncommon.

20 [0004]

The reason why the application of the melted weld-deposition coating of the self-fluxing alloy for the boiler tube is uncommon is that an extraordinary difficult work is required because in which since the thermal shock cracking easily occurs is easy to occur for the boiler tube on its melted weld-deposition coating 25 under caused by rapid local temperature rise at the time of the welding operation when the boiler tube is welded to connect to be joined for use, the whole tubes

~~have to be preheated~~ are subjected to preheating inside the furnace, then
~~connected by welding at the tube with high temperature is made to be joined by~~
~~the welding.~~

However, as for the boilers in recent years, the problems concerning not
only erosion but also corrosion are becoming become important together with the
demand for high-temperature burning to make the request for making exhaust air
harmless, thus melted weld deposition coating application to the boiler is
increasingly desired earnestly in the form of provision of prefabricated coating
portion.

[0005]

As one example thereof, a constitution that adopted the melted weld-
deposition coating of the self-fluxing alloy is applied to the boiler tube is disclosed
in the patent document 1 (Japanese Patent Application Laid-Open (JP-A) No.
H10-170194). ~~There the Then, here there is adopted~~ constitution provides in
which a non-coated thermally sprayed portion of about 50 mm is provided at an
end portion of the boiler tube, excluded from the thermally sprayed coating where
which the non-coated thermally sprayed portion is used taken to as a part for the
joint (the patent document 1, margin (page 3, the fourth column, lines 15 to 16; in
the patent document 1). Further, a process of fitting a protector member on the
above non-coated thermally sprayed portion is added, after the welding, process-
of fitting a protector member instead of the coating, after the welding (Id. is
added (the fourth column, lines 24 to 26). The above process requires a special
order of the protector member (for example, the protector member made of
alumina) having high provided with the excelling in erosion resistance, or fitting
operation inside narrow boiler, Therefore, therefore, it is necessary for the process
results in higher to prepare high-cost in material and work, and also requires front

loaded procurement of the materials.

[0006]

As for ~~another approach, one may imagine a method~~ In addition to this, technique that adopts welding to connect prefabricated boiler tubes having
5 unmelted coating of after the weld joint a self-fluxing alloy, ~~non-thermally-sprayed~~
~~coating boiler tube prefabricated inside the factory at the construction site, and~~
then apply the melting process by an due to the induction heating or the like is
made to be applied at that location. ~~However can be considered, however, it is~~
impossible practically impossible due to caused by the narrow space or heating-
10 difficulty in heating of the interfaced portion with the other members.

By the way, since, ~~in the melting process of the self-fluxing alloy,~~
reheating-crack occurs unless when the entire simultaneous melting or one
direction melting is ~~not performed in the melting process of the self-fluxing alloy,~~
the induction heating is indispensable for such an execution at the construction
15 site that location.

[0007]

Next, in the case of the boiler furnace panel, since it is composite
constitution in which tube materials and plate materials are arranged alternately as
described above, or since it has large dimension (for example, 0.5m × 6m), use of
20 a practical supplemental member corresponding to the above protector is more
difficult. ~~Further, further~~ there is the problem of the complicated shape distortion
associated together with the melting process after the thermal spraying (see the
patent document 2 or the patent document 3). ~~Thus, thus the condition is that~~
utilization of the prefabricated melt-coating product itself has been is difficult to
25 consider under such circumstances.

[0008]

Patent Document 1: JP-A No. 10-170194

5 **DISCLOSURE OF THE INVENTION**

Problem to be solved by the Invention

[0009]

The first problem is to provide an alloy-coated boiler part that is coated with melted coating of alloy material with high erosion and corrosion resistance at
10 all regions to be protected,~~is subjected to a weld deposition coating of alloy material excelling in erosion/corrosion resistance~~ and that even when joined by the welding,~~is free from thermal shock cracking~~ even when joined by the welding.

Further, the second problem is to provide a method of welding a self-fluxing alloy coated boiler ~~parts to part in~~ which the melted coating of the
15 self-fluxing alloy has been applied at all regions, where the method enables the welding for joining the boiler part and so on ~~to which the weld deposition coating of the self-fluxing alloy is applied at all regions can be performed~~ free from thermal shock cracking.

Means for Solving the Problems

20 [0010]

The alloy coated boiler part according to the present invention described in ~~claim 1~~ has been ~~is~~ devised for solving the above mentioned first problem and
is ~~characterized~~ in that

an alloy coated boiler part used by being welded to be joined, which is
25 constituting of a base metal and constituted such that a coating composed of an alloy coating applied thereon, where the alloy material is comprising of ~~occupied~~

by an Ni (Nickel)-enriched Ni-Cr (chromium) component with over a half proportion of the alloy material, _

a melted is applied to a base metal, and which the alloy coated boiler part is used by being welded to be joined, a weld deposition coating composed of said alloy material further comprising of reduced(the second alloy material) in which contents of B (Boron) and Si (Silicon) as being melting point lowering elements with are suppressed such that B is 0.1 weight % or less B and Si is weight ratio 0.5 weight % or less Si (the second alloy material), is applied over rapid-temperature rise region, where thermal shock cracking may occur at the welding operation, at end portions subjected to weld joint including the vicinity thereof, where thermal shock cracking may occur due to a rapid temperature rise at the welding operation, and

, on the other hand, a melted weld deposition coating of said alloy material further comprising of B and Si with each content in the range of 1 to 5 weight % (any of 1% or more and 5% or less) (the first alloy material), is applied (desirably by after-thermally sprayed melt-coating) composed of said alloy material (the first alloy material) of composition in which contents of B and Si are in the range of 1 to 5% respectively (any of 1% or more and 5% or less) is applied on any remaining regions other than areas subject to the rapid temperature rise, _

region.—By the way, as for a forming means of the melted weld-deposition coating composed of the above second alloy material, there can be exemplified the weld building-up (one layer building-up if of importance is given to cost, or two layers building-up if of importance is given to component purity), although however, being not limited to such this method.

[0011]

Further, a method of welding a self-fluxing alloy coated boiler part

according to the present invention ~~described in claim 8~~ is devised for solving the above mentioned second problem, being a method of welding self-fluxing alloy coated boiler part where a melted ~~to which a weld deposition~~ coating (desirably after-thermally sprayed melt-coating) composed of a self-fluxing alloy material (the first alloy material) occupied by an Ni-enriched Ni-Cr component over a half proportion of the alloy material and further occupied by B and Si in the range of 1 to 5 weight % respectively ~~(the first alloy material)~~ is applied to a base metal, the method is characterized by comprising the steps of:

forming a gradation preheated region, around the end portion ~~with end-
portions~~ subjected to the welding ~~as the objects~~, upon applying preheating process having a heating pattern where an amount of temperature raising gradually reduces inward from the end portion ~~portions~~ by using slow heating condition with a ~~that~~ speed of temperature raising at said end portions of is 2 to 10°C/sec; and

performing a welding operation of said end portions continuously (desirably, with the second alloy material occupied by an Ni-enriched Ni-Cr component over a half proportion of the alloy material and having the reduced contents of B and Si with ~~are suppressed such that B is 0.1 weight % or less for B and Si is weight ratio 0.5 weight % or less for Si.)~~

~~) of said end portions continuously.~~ By the way, in the above welding operation, also a weld building-up operation for the end portion of single part and weld joint of the end portions of neighboring parts are included.

Effect of the Invention

[0012]

The alloy coated boiler part ~~described in claim 1~~ of the present invention is constituted such that the melted weld deposition coating composed of the alloy

material (~~the first alloy material~~) having fusibility with melting point lowering elements sufficiently mixed (~~the first alloy material~~) has been applied at the most area except for the end portions. ~~Thus, portion is applied, as for the end portion,~~ thus manufacture in a factory with high productivity and low cost in the same as ~~those of~~ ordinary thermal spraying-melting process can be performed. On the other hand, the end portion region has no choice but to depend on high cost implementation other than the thermal spraying such as the weld building-up or the like with low productivity. ~~However, however, since the region area is small, it~~ is possible to manufacture with a low cost as a whole, since the region area is
10 small entire.

The melt thermal-spraying coating of the end portion region keeps the mixing amount of B, Si to a minimum, that is, the thermal coating is composed of the second alloy materials. ~~Therefore, therefore, there is no fusibility, thus high~~ implementation-productivity cannot be desired. ~~However, however, instead of~~
15 this, the end portion region is free from the thermal shock cracking sensitivity which the alloy material with sufficiently high concentration of mixed with B and Si exhibits has.

With respect to durability, since the both coatings are the melt thermal-spraying coatings, the environment blocking property is sufficient, further, also the
20 corrosion resistance of the coating itself is significantly excellent due to high Ni-Cr composition. With respect to erosion resistance, the coating for the most region being composed of coating to which large amount of B, Si are mixed excels. ~~However, since the, however, it has no great difference is not serious,~~ a treatment to a degree of adding difference to an initial coating thickness is capable of
25 approximately equalizing the erosion resistance.

As described above, the first problem is solved.

[0013]

According to the method of welding the self-fluxing alloy coated boiler part of claim 8, as for the thermal shock cracking of the self-fluxing alloy melted thermally sprayed coating generated caused by rapid temperature rise at the time of the welding, it is possible to minimize rapid change amount of temperature accompanied with the rapid temperature rise over the entire region, thus the thermal shock cracking is not generated by providing "gradation preheated region" in such a way as to involve filler metal applied application region. Because, it is possible to minimize the amount of rapid change of temperature over the entire region accompanied with the rapid temperature rise.

The above described welding method is useful available when a necessity of rapid preparation of adjusting the alloy coated boiler part of constitution of claim 1 is required due to an a unexpected condition such as dimension adjustment collaboration in the boiler construction site. For example, it is possible to prepare the alloy coated boiler part equivalent to the product having been adjusted at the construction site, and free from the thermal shock cracking even when supplied for welding being subjected to weld for joining, in following procedures; the self-fluxing alloy at that construction site, which the alloy-coated boiler part with melted coating is the same as the product described in claim 1 and is adjusted to the collaboration dimension in such a way that the self-fluxing alloy thermal spraying-coated boiler part manufactured in the factory is at first adjusted in dimension; then the coating of the self-fluxing alloy (the first alloy material) of the end portion is removed; and made to adjust to the collaboration dimension; further, the weld building-up is performed to the end portion with where the alloy material (desirably, the second alloy material) of the composition for the end portion (desirably, is taken to as the second filler metal after removal of the coating of the

self-fluxing alloy (the first alloy material) of the end portion. Or it is possible to perform repair of the self-fluxing alloy coating by applying the above described pre heating-weld building-up to the coating defect portion (exfoliation portion or the like) of in the member on which is subjected to the self-fluxing alloy coating (the thermal sprayed coating or un-melted coating) has been applied.

[0014]

Here, the gradation preheated region prepared before the building-up implementation is capable of being formed as gradual with gentle temperature distribution by using ~~procedure of operation to swing appropriately a solenoid coil in the axis line direction thereof upon performing~~ induction heating using the solenoid coil in which winding density is gradually changed along in the axis line direction so as to generate a gradient of heat input density along the axis line direction and by incorporating procedure of swinging a solenoid coil appropriately in the axis line direction.

The above preheating process is somewhat troublesome work. However, it is possible to implement reasonably in a narrow space inside the boiler, since, ~~however,~~ the object region is an only extremely narrow range, and further, a it is sufficed if preparing minimum scale of a high frequency power supply is required, ~~therefore, it is possible to implement reasonably in a narrow space inside the boiler.~~

By the way, the preheating in this welding method may be performed efficiently by is efficient depending on the induction heating as described above. However, ~~however,~~ being not limited to this, it may be substituted by other heating method, such as, for example, gas heating.

[0015]

Above described procedure is significantly effective in when rapidly forming and saving beforehand at the boiler construction site the ~~the~~ easily weld-

jointing alloy coated boiler part described in claim 1 that are easily jointed by welding at the boiler construction site.

The above described welding method, further, it is also useful available when intended to perform welding joint of the self-fluxing alloy thermally spraying-coated boiler part having melted coating and cut in actual dimensions collaboration dimension without generating thermal shock cracking at all events in ~~stead of~~ preparation at that construction site in stead of preparing of the alloy coated boiler part described in the above claim 1; thus it becomes a temporary measure of corresponding to the boiler parts with a uniform alloy coating one-article-
10 correspondence instead of provision of the alloy coated boiler part described in claim 1.

In the method of welding the self-fluxing alloy coated boiler part described in claim 8, it is desirable that the alloy material (~~the second alloy material~~) of the composition for the end portion (the second alloy material) is set to a filler metal
15 while considering quality requirement (erosion/corrosion resistance) after the welding.

As described above, the second problem is solved.

25

BEST MODE FOR CARRYING OUT THE INVENTION

[0016]

Constitution of one embodiment of the alloy coated boiler part of the present invention will be described while referring to the drawings. Figs. 1(a) to Fig. 1(e) show structure of a boiler furnace panel 10 as the specific example of the alloy coated boiler part, in which Fig. 1(a) is the entire plan view; Fig. 1(b) is the entire front view/end elevational view s; Fig. 1(c) is an enlarged plan view of the major portion; Fig. 1(d) is a principal part enlarged front view/end elevational view; Fig. 1(e) is cross section enlarged view; and Fig. 1(f) is a plurality of joined state plan view.

[0017]

The boiler furnace panel 10 is one in which a super alloy coating 15 (the second alloy material coating) and a self-fluxing alloy coating 16 (the first alloy material coating) are thermally sprayed to a steel panel 11 (a base metal) at a factory beforehand, on the occasion of assembling of the furnace housing, neighboring end portions each other are weld joined while overlapping a plurality of panels at the construction site. That is, a steel panel 11 (plate material-tube material composite panel) is constituted such that, in order to form a base unit of furnace housing with a cooling water passage, a tube portion 12 (tube material) forming a cooling water passage and a plate portion 13 (plate material) forming a joint portion are arranged alternately and these are joined tightly with weld joint or the like, further, for erosion/corrosion resistance, at the one side (portion to be protected) of the housing, being furnace inner wall, except for end portions for weld joint, weld sprayed coating composed of the alloy material is formed on the entire area.

[0018]

In the thermal spraying, the super alloy coating 15 and the self-fluxing

alloy coating 16 are used separately for reduction of the cost of material and the cost of construction, in which the super alloy coating 15 is carried out at belt shaped region (rapid temperature rise region) in the end portions of a tube end side provided to weld joint portion 20 among panel end portions, while the
5 self-fluxing alloy coating 16 is carried out at remaining region among region to be protected. The rapid temperature rise region is a region in which the thermal shock cracking may occur in self-fluxing alloy coating at the time of the weld operation, since the rapid temperature rise region width C differs depending on a steel material shape or coating thickness or the like, it cannot be described
10 sweepingly, but, in the boiler furnace panel, it may be about 15 to 50mm (any of 15mm or more and 50mm or less).

[0019]

Of course, with respect to the end portion of the plate portion 13, the super alloy coating 15 is formed up to inner portion exceeding it. That is, the
15 super alloy coating 15 enters into not only the rapid temperature rise region but also the remaining region which is a region exceeding it while extending up to about two times of the rapid temperature rise region width C. Further, at that position, a thin notching 14 with a width of about 0.5 to 2mm is formed. This secures warping margin for weld aligning of the tube portion 12, and may extend
20 to a degree of several times of the rapid temperature rise region width C together with the super alloy coating 15 of the end portions of the plate portion 13 depending on thickness of the tube portion 12. At end portion surface of the tube portion 12, large chamfer/taper to become a welding groove is provided.

[0020]

25 The material of the super alloy coating 15 is occupied by an Ni-enriched Ni-Cr component over a half proportion of the alloy material, however, contents of

B and Si being melting point lowering elements are suppressed such that B is 0.1% or less and Si is 0.5% or less for avoiding a thermal shock cracking at the time of the welding operation. As standards for stipulating such alloy material, in Japan, there are listed JIS G 4901 for bar material, or JIS G 4902 for plate material, as International standards, there are listed ISO 4955, or ISO 9723. Thickness of the super alloy coating 15 is about 1.2 to 3.0 mm.

[0021]

The material of the self-fluxing alloy coating 16 is occupied by an Ni-enriched Ni-Cr component over a half proportion, and contents of B, Si are set to 1 to 5% (weight ratio) respectively in order that steep rise of material cost is made to suppress and efficient implementation is brought by the thermal spraying process and the melting process. As the alloy material, in Japan, there is listed Nickel self-fluxing alloy material of composition stipulated in a JIS H 8303. In other countries or areas, there is listed Nickel self-fluxing alloy material of composition stipulated in International standards ISO 14920. By the way, as the self-fluxing alloy material, though high price, Co (cobalt) based self-fluxing alloy material or WC (tungsten carbide) mixed self-fluxing alloy material may be used as the need arises. Thickness of the self-fluxing alloy coating 16 is about 1.0 to 2.0 mm.

[0022]

A manufacturing process concerning the boiler furnace panel 10 (alloy coated boiler part) of the embodiment will be described referring to the drawings. Fig. 2(a) is the entire plan view; Fig. 2(b) is the entire front view/end elevational view; Fig. 3(a) is an enlarged plan view of the major portion; Fig. 3(b) is an enlarged plan view of the major portion; Fig. 4(a) is an enlarged plan view of the major portion; Fig. 4(b) is a major portion enlarged front view/end elevational

view; Fig. 4(c) is the entire plan view; Fig. 4(d) is the entire front view/end elevational view; Fig. 4(f) is the entire front view/end elevational view; Fig. 5(a) is an enlarged plan view of the major portion ; and Fig. 5(b) is a major portion enlarged front view/end elevational view.

5 [0023]

The manufacture of the boiler furnace panel 10, in short, is one in which a steel panel 11 is taken to as a base metal, a super alloy coating 15 is formed on an one side of the steel panel 11, after that, also a self-fluxing alloy coating 16 is formed thereon, and further, end portion shape is finished, being performed in a
10 factory.

The steel panel 11 (see Fig. 2) is preferable in the same as conventional one in which the tube portion 12 and the plate portion 13 composed of steel materials are joined alternately by the weld joint or the like. In the case of ordinary boiler furnace panel, size of the steel panel 11 is in the dimension that
15 length is about 4000 to 6000 mm and width is about 400 to 500 mm, diameter of the tube portion 12 is about 60 to 75 mm, thickness of the tube portion 12 is about 5.0 to 7.0 mm, and thickness of the plate portion 13 is about 5 to 7 mm.

[0024]

Formation of the supper alloy coating 15 concerning the end portion of the steel panel 11 (see Fig. 3), in the tube portion 12, is performed to somewhat
20 wider range than the rapid temperature rise region width C, while, in the plate portion 13, being performed to a portion come further inwardly. By the way, in some cases, the tip of about 50 to 150 mm remains without performing coating process for fixing and keeping of the work during operation, however, at that case,
25 it is cut off at the time of end portion shape finishing. Implementation work of the super alloy coating 15 is performed with the weld building-up, the second alloy

material being made into a wire material is suited as a filler metal, above all, in Japan, the super alloy materials stipulated in JIS G 4901-NCF 625, and JIS G 4902-NCF 625 are suitable, while in other countries or areas, it is possible to select corresponding article from the super alloy materials stipulated in international standards of ISO 4955 or ISO 9723 or the like.

[0025]

Formation of the self-fluxing alloy coating 16 to the remaining region of the rapid temperature rise region (see Fig. 4) is performed in the order of masking of the super alloy coating 15, thermal spraying of the self-fluxing alloy, and melting process of the self-fluxing alloy. By the way, although detailed description is omitted, surface cleaning process such as shot blast and the like is performed appropriately. Masking of the super alloy coating 15 is performed using, for example, a blocking plate such as metal thin plate or the like, or heat-resistant masking tape. Further, the masking is performed such that the super alloy coating 15 is partially overlapped on the self-fluxing alloy coating 16 in order that a base metal is not exposed from a gap formed between the super alloy coating 15 and the self-fluxing alloy coating 16. In such overlapped portion, it is preferable to add taper in thickness of the both coating so that a sudden difference in level does not emerge.

[0026]

Since the thermal spraying and the after melting process for the formation of the self-fluxing alloy coating 16 is preferably performed in such a way as coating formation process to a conventional article with no super alloy coating 15 (for example, see the patent document 2), although detailed description is omitted, it is performed with ordinary procedure by using known apparatus. That is, thermal spraying of the self-fluxing alloy is performed efficiently with ordinary thermal

spraying method by using known thermal spraying apparatus. As for the thermal spraying material of the self-fluxing alloy coating 16, the first alloy material powdered is suited, above all, in Japan, nickel self-fluxing alloy material corresponding to JIS H 8303-SFNI 4 is preferable, in other countries or areas, it is possible to select corresponding article from nickel self-fluxing alloy materials stipulated in the international standards of ISO 14920.

[0027]

Further, basically, the melting process of the self-fluxing alloy is performed efficiently in one direction with ordinary movement heating method by using known high frequency induction heating apparatus.

However, different from the conventional method, sufficient thermal spraying process is made to bring under the condition of one directional movement to the self-fluxing alloy coating 16 thermally sprayed to the plate portion 13 (see patent documents 2, 3).

[0028]

In the case of coating with the above alloy materials, it is preferable to set thickness ratio between the super alloy coating 15 and the self-fluxing alloy coating 16 into 1.2 to 2.0 : 1. This is because wear-resistance of the self-fluxing alloy coating is superior to the super alloy coating, thus, by presetting the coating thickness ratio of the above range depending on conditions, wear-resistant service life of the both coatings are equalized. That is, in less than 1.2 : 1, wear of the super alloy coating 15 precedes, there is a fear that remaining self-fluxing alloy coating 16 becomes useless, on the other hand, exceeding 2.0 : 1, inversely wear of the self-fluxing alloy coating 16 precedes, there is a fear that remaining super alloy coating 15 becomes useless.

[0029]

After formation of the alloy coatings 15, 16 on one side of surface, un-coated portion of the tip of the steel panel 11 is cut off (see Fig. 5). This is done by a plasma cutting or the like, simultaneously or another time, a notch 14 is formed. Further, chamfering process is carried out at the tip of the tube portion
5 12 while preparing for weld joint for another boiler furnace panel 10 (see Figs. 1(c), 1(e)).

Thus, when terminating the finishing of the end portion, one of the boiler furnace panel 10 is completed. Further, similarly, when the boiler furnace panel 10 is efficiently manufactured one after another, these are accumulated to be kept
10 in a factory or warehouse or the like.

[0030]

Use state concerning the boiler furnace panel 10 (alloy coated boiler part) of the embodiment will be described referring to the drawings. Since a plurality of boiler furnace panels 10 are assembled into a boiler furnace with the plurality of
15 panels with weld-joining, here, particularly there will be described weld process of the boiler furnace panels 10 each other. Fig. 6(a) is a cross sectional view showing the weld joint portion before the implementation of welding process of the alloy coated boiler part; and Fig. 6(b) is an enlarged cross sectional view showing the weld joint portion after welding of welding process of the alloy coated
20 boiler part. Further, Fig. 1(f) is a plan view showing a joined state of a plurality of the boiler furnace panels 10.

[0031]

Weld joint process comprises positioning (aligning) process, tube end portion weld joint process and plate portion weld joint process, under that order,
25 treatment of each process is applied to weld joint portion 20 of a pair of weld object boiler furnace panels 10. In some cases, this is partially performed in

assembling factory, however, this is performed finally in a boiler construction site.

Firstly, in the positioning process (see Fig. 6(a)), both boiler furnace panels 10 are fixed in the state that the tip end portions of tube part 12 to become the weld joint portion 20 are caused to face. Then, if there is position deviation in each tube end portions faced state, and the position deviation is slight one which is generated by formation of the alloy coatings 15, 16, position adjustment of the faced tube end portions is performed by knocking a small weld portion into the notch 14 and the like.

[0032]

Next, in the tube end portion weld joint process (see Fig. 6(b)), annular welding is performed from a tube inner surface side to a tube outer surface side for several times for no generation of voids, and for no overheating. In the shown example, since being separated in five layers, the welding starts from the annular welding of a super alloy welding layer 21 facing on hollowness of the tube, followed by the annular welding of a super alloy welding layer 22 buried with the tube thickness, further, three columns of super alloy welding layers 23, 24 and 25 exposed on the tube outer periphery are carried out sequentially every one round. As for the filler metal used in the tube end portion welding process, the second alloy material as being the super alloy coating 15 is desirable in the point of balance of corrosion resistance, and wear resistance to the self-fluxing coating. The super alloy coating 15 carried out using the second alloy material has no thermal shock cracking sensitivity, therefore, the welding is performed easily and accurately without injuring the coating. Further, as for the self-fluxing alloy coating 16 ahead of it, though having the thermal shock cracking sensitivity, since the super alloy coating 15 covers the rapid temperature rise region width C, also, it is not necessary for concerning a generation of cracking.

[0033]

Finally, in the plate portion weld joint process, although illustration is omitted, an application plate with a size for covering at least both notches 14 is welded while extending over the plate portion 13 of the both boiler furnace panels

- 5 10. The welding of the application plate is performed from the other side (that is, un-formed surface of the super alloy coating 15, furnace outer wall surface or unprotected surface). The notch 14 is thin and further change of the application plate is easy, therefore, in some cases, process is terminated by leaving inner side of the notch 14 in the state of the base metal as it is, that is, the inner side of the
- 10 notch 14 is left such that the steel panel 11 is exposed, however, it may be preferable to fill up in the notch 14 with the welding while using the second alloy material as being the super alloy coating 15 as the filler metal. Further, as for the plate portion 13, different from the tube portion 12, since the repair after the boiler construction is easy to perform (even the repair being performed from
- 15 outside the boiler, rough object can be achieved), it may be adopted the procedure that, after realizing long service life while thickening a panel end portion plate or plate thickness of the application plate, the alloy coating is omitted.

[0034]

- Thus, the boiler furnace panel 10 is joined to one after another (see Fig. 20 1(f)), the furnace housing with cooling water passage is completed.

[0034]

- In such a furnace housing, the entire region concerning the entire surface of inner wall, or portion to be protected of the inner wall surfaces, are covered with close alloy coating, thereby, erosion/corrosion resistance is improved
- 25 significantly.

[0035]

Next, processes concerning one embodiment of the method of welding the self-fluxing alloy coated boiler part of the present invention will be described referring to the drawings. Fig. 7(a) is a plan view of a boiler tube; Fig. 7(b) is a plan view/end elevational view of a boiler tube; Figs. 7(c) to 7(h) are plan views of a boiler tube; and Figs. 8(a) and 8(b) are plan views of a boiler tube.

[0036]

Here, there will be described supplying method of the boiler tube at the construction site which the boiler tube is not prepared beforehand. Provided that the steel boiler tube 70 subjected to the self-fluxing alloy coating on outer circumferential surface being a portion to be protected (see Figs. 7(a), 7(b)) can be obtained rapidly, however, its length does not agree with the assembling portion (see Fig. 7(c)). Further, the self-fluxing alloy coating is alloy material occupied by Ni-enriched Ni-Cr component over a half proportion of the alloy material, and in which B and Si are mixed in the range of 1 to 5% respectively, that is, the self-fluxing alloy coating is the first alloy material (above described material of the self-fluxing alloy coating 16) having the thermal shock cracking sensitivity, when it is welded in the state that self-fluxing alloy coating 16 is left as it is, the welding becomes not desired state.

[0037]

Accordingly, an adaptation portion with required length is made to remain by cutting off a surplus portion 71 from the boiler tube 70 (see Fig. 7(d)), for after weld joint (see Fig. 8(b)), firstly, performed is the welding of the weld building-up at both end portions of the adaptation portion 72 being the adoption portion (see Figs. 7(e) to 7(h), and Fig. 8(a)). The process order of the welding is described in detail, firstly, the self-fluxing alloy coating is removed from the both end portions 73, 74 within the adaptation portion 72 (see Fig. 7(e)). The base metal exposed

width of the end portions 73, 74 are the same as the above described rapid temperature rise region width C, though cannot be described indiscriminately, being about 15 to 50 mm.

[0038]

5 After that, an induction coil 75 configured such that the coil 75 is wound in a solenoid shape and its winding pitch increases monotonously (see Fig. 7(f)) is made to connect to the high frequency induction heating apparatus; the end portion 73 is inserted to be fitted with freedom into the coil 75 (see Fig. 7(g)), to perform preheating process due to induction heating. At this time, an induction
10 coil 75 which has a length of 2 to 3 times of base metal exposed width in the end portion 73 is used, where rough portion of the winding pitch is set to an intermediate portion side of the adaptation portion 72 while dense portion of the winding pitch is set to the end portion 73 side between both end portions of the induction coil 75. Further, energizing condition of the induction coil 75 set on the
15 high frequency induction heating apparatus is made a gradual speed heating condition that a temperature raising speed in the end portion 73 becomes 2 to 10°C.

[0039]

20 Then, the adaptation portion 72 is preheated slowly with heating pattern where the amount of temperature rise gradually decreases inwardly from the end portion 73. Subsequently, if the temperature of the maximum temperature portion becomes 450 to 600°C, the heating ends. By this means, "gradation preheated region" with no sudden change in a respect of space in axial direction and in respect of elapse of time is formed, therefore, consecutively, that is, swiftly
25 before being cooled, the super alloy coating 76 is formed at the end portion 73 of the adaptation portion 72 (see Fig. 7(h)). The formation is performed such that,

with the weld building-up, no base metal exposed surface is made to leave at the position between the self-fluxing alloy coating and the super alloy coating 76.

[0040]

Further, in the weld building-up, the second alloy material (above
5 described the material of the super alloy coating 15) with no thermal shock
cracking sensitivity is used as the filler metal. That is, the alloy material occupied
by an Ni-enriched Ni-Cr component over a half proportion of the alloy material and
contents of B and Si being melting point lowering elements are suppressed such
that B is 0.1% or less and Si is 0.5% or less is taken to as the filler metal, and the
10 welding is performed.

In such a welding, previous formation is the self-fluxing alloy coating, and
after formation is the super alloy coating, however, the welding is carried out
within the "gradation preheating region", therefore, there is no chance of cracking
the self-fluxing alloy coating.

15 [0041]

Thus, the adaptation portion 72 of the boiler tube 70 is constituted such
that, as for the end portion 73 being an object region of the later weld joint, the
super alloy coating by the second alloy material is formed extending over the rapid
temperature rise region, and, at the inner remaining region from the super alloy
20 coated region, the self-fluxing alloy coating is left. Then, if the same welding is
performed with respect to the remaining end portion 74, the corresponding boiler
tube 80 to the boiler furnace panel 10 described above is completed (see Fig.
8(a)). Also the other tubes 81, 82 joined to the boiler tube 80 are prepared
similarly at the construction site if necessary, and then being kept temporarily.

25 [0042]

Then, at the time of the weld joint, the boiler tubes 80, 81 and 82 as

being joining object are arranged at the construction site, after performing the required pipe end portion treatment such as formation of the welding grooves, the boiler tubes 80, 81 and 82 are made to fix with the condition that the tips of the boiler tubes 80, 81 and 82 are oppositely faced to each other at the weld joint portions 83, 84 (see Fig. 8(b)). Then, the weld joint of the pipe end portions is performed to the respective weld joint portions 83, 84 while using the same filler metal used for the weld building-up of the super alloy coating 76. The tube end portion weld joint of the boiler tube 80, like the tube end portion weld joint of the tube portion 12 described above, can be performed easily without a concern of the thermal shock cracking of the self-fluxing alloy coating, and the preheating is not necessary.

[0043]

Processes concerning the other embodiment of the method for welding the self-fluxing alloy coated boiler part of the present invention will be described referring to the drawings. Figs. 9(a) and 9(b) are plan views of major portions of a boiler tube.

[0044]

Here, there will be described the weld joint method when it becomes necessary to perform the weld joint of the steel boiler tubes 90 subjected to the self-fluxing alloy coating on the outer circumferential surface at the construction site in a hurry. Here, also, since the self-fluxing alloy coating is alloy material occupied by Ni-enriched Ni-Cr component over a half proportion of the alloy material, and in which B and Si are mixed in the range of 1 to 5% respectively, that is, the self-fluxing alloy coating is the first alloy material (above described material of the self-fluxing alloy coating 16) having the thermal shock cracking sensitivity, when it is welded in the state that self-fluxing alloy coating 16 is left as

it is, the welding becomes not desired state, there is performed formation of the "gradation preheated region" by using the high frequency induction heating apparatus.

[0045]

5 Reasonably, the preheating of this case, different from the above described respective embodiments, is performed immediately before the weld joint. Further, in many cases, the both boiler tubes 90 of the joining object are already fixed at the construction site, and it is difficult to separate the both end portions 91. For that reason, it is preferable that the end portion 91 is subjected to
10 pre-processing of forming the weld grooves, while, for the induction coil 92, one-turn article capable of acting in deployment, and put on and taken off is adopted (see Fig. 9(a)). Then, when performing the heating for formation of the "gradation preheated region" while high frequency energizing the induction coil 92, the induction coil 92 is caused to reciprocate.

15 [0046]

The reciprocating movement is performed many times until the temperature of the maximum temperature portion arrives at 450 to 600°C. Further, the heating is performed at the region of the end portion 91 in gradual speed, to the contrary, with being separated from the end portion 91 in rapid
20 speed, in order that the heating pattern becomes a pattern where the amount of temperature rise gradually decreases with heading toward the both directions, with the end portion 91 of the weld joint object as the center, that is, the heating pattern becomes a pattern where the amount of temperature rise gradually decreases with heading inwardly in longitudinal direction of the boiler tube 90 from
25 the end portion 91. The reciprocating distance, at one side, that is, with respect to one boiler tube 90, of about 15 to 50 mm is secured inwardly from the end

portion 91. Further, in this case also, energizing condition of the induction coil 92 set to the high frequency induction heating apparatus is set to gradual speed heating condition such that the temperature raising speed in the end portion 91 becomes 2 to 10°C/sec.

5 [0047]

Then, also in this case, "gradation preheated region" with no sudden change in respect of space in axial direction and in respect of elapse of time is formed, therefore, consecutively, faced end portions 91 of the boiler tube 90 are made to perform weld joint swiftly (see Fig. 9(b)). The weld joint of the weld joint portion 93, like the tube end portion weld joint of the tube portion 12 described above, is performed in which the second alloy material (above described material of the super alloy coating 15) with no thermal shock cracking sensitivity is taken to as the filler metal. That is, in this case also, the filler metal is the alloy material occupied by an Ni-enriched Ni-Cr component over a half proportion thereof and contents of B and Si are suppressed such that B is 0.1% or less and Si is 0.5% or less, however, since the gradation preheating precedes immediately before, there is no case where the self-fluxing alloy coating is cracked.

[0048]

The others, in the above described respective embodiments, as the specific example, production in the factory of the boiler furnace panel 10 and obtaining in construction site of the boiler tube 80 are described, however, there may be the reverse. That is, like the above description, also production of the boiler tube 80 in the factory, and obtaining the boiler furnace panel 10 in the construction site are appropriately performed, though the detailed description as being repetition is omitted.
